Precoccygeal epidermal inclusion cyst presenting as coccygodynia

Jaiswal A, Shetty A P, Rajasekaran S

ABSTRACT
Although there are numerous aetiologies for coccygodynia described in the medical literature, precoccygeal epidermal inclusion cyst presenting as a coccygodynia has not been reported. We report a 30-year-old woman with intractable coccygodynia. Magnetic resonance imaging showed a circumscribed precoccygeal cystic lesion. The removed cyst was pearly-white in appearance and contained cheesy material. Histological evaluation established the diagnosis of epidermal inclusion cyst with mild nonspecific inflammation. The patient became asymptomatic and remained so at two years follow-up. This report suggests that precoccygeal epidermal inclusion cyst should be considered as one of the differential diagnosis of coccygodynia. Our experience suggests that patients with intractable coccygodynia should have a magnetic resonance imaging to rule out treatable causes of coccygodynia.

Keywords: coccygodynia, coccyx, epidermal inclusion cyst, precoccygeal epidermal inclusion cyst

INTRODUCTION
Intractable coccygodynia is frequently-labelled as being idiopathic or post-traumatic, but various other aetiologies of coccygodynia have been described, usually in the form of sporadic individual case reports. We report a previously-undescribed case of precoccygeal epidermal inclusion cyst as cause of coccygodynia, which stresses the importance of advanced investigations for confirmation of diagnosis. A thorough literature review was done to evaluate the various aetiologies of coccygodynia.

CASE REPORT
A 30-year-old nulliparous female patient presented with severe pain in the coccygeal region of five years’ duration. The pain was insidious from onset without any antecedent trauma, localised, initially intermittent but continuous for the last two months. Sitting and reclining backwards aggravated the pain. There was no radiation, neurological symptoms, constitutional symptoms, difficulty in defaecation or micturition. She had undergone conservative treatment in the form of rest, doughnut ring, local heat, and avoidance of direct pressure over the area, with only partial relief. Physical examination revealed normal overlying skin and marked tenderness over the coccyx on deep pressure. Rectal examination revealed an extra luminal retrorectal tender swelling. Radiographs showed type 1 morphology (Postacchini and Massobrio) of coccyx without any evidence of fracture or erosion. There was no instability in the form of subluxation or hypermobility in lateral dynamic views. Haematological investigations including erythrocyte sedimentation rate and C-reactive protein were noncontributory. Magnetic resonance (MR) imaging showed a 1.5 cm precoccygeal cystic lesion with well-circumscribed margins. The contents of the cyst appeared isointense on T1- and hypointense on T2-weighted images (Figs. 1 & 2).
Resection of the coccyx and cyst was done with the patient in prone position, using a posterior longitudinal midline incision, careful subperiosteal dissection, coccygectomy and meticulous extirpation of the cyst. The cyst was pearly white in appearance and contained cheesy material. The histological sections of the biopsy demonstrated keratinaceous debris circumscribed by stratified squamous epithelium (Fig. 3). There was no evidence of malignancy. There was a mild, nonspecific chronic inflammation in the cyst wall. There were no granulomata. The histological diagnosis was epidermal inclusion cyst. The patient was completely relieved of symptoms and continued to be asymptomatic at two years follow-up.

**DISCUSSION**

Coccygodynia is a common entity seen in orthopaedic and spine clinics. The term, coccygodynia, was coined by Simpson in 1861 for painful coccyx.\(^\text{15}\) Though it is often being referred to as a disease, it actually describes a symptom. Intractable coccygodynia can be a very debilitating disorder. Although mostly labelled as idiopathic or post-traumatic in origin, various unusual pathological conditions have been described as a cause for coccygodynia.\(^\text{4-14}\) Initially thought to be a neurotic disorder, it is now known that there is not much difference in psychological profiles of symptomatic and asymptomatic people.\(^\text{12}\) Other suggested aetiologies\(^\text{20}\) of idiopathic coccygodynia are spasm of the muscles of the pelvic floor,\(^\text{16}\) anomalies of the soft tissues in the mid-sacral region, chronic inflammation of an adventitious coccygeal bursa, and arachnoiditis of the lower sacral nerve roots. Morphological abnormality of the coccyx, including increased intercocygeal angle,\(^\text{1-2}\) spicule,\(^\text{1-2}\) retroversion,\(^\text{17}\) and scoliosis,\(^\text{18}\) may be possible causes of idiopathic coccygodynia. Initially, it was thought that even lumbosacral disc prolapse can present as coccygodynia.\(^\text{19}\) However, the fact that a substantial number of patients showing successful outcomes with treatment localised to the coccyx refutes the theory of discogenic origin of pain.\(^\text{20}\)

Since coccygeal pain often develops after a local injury, it has been most frequently attributed to causes involving trauma. Antecedent trauma due to falls or difficult vaginal delivery can directly injure sacrococcygeal synchondrosis. Furthermore, obesity decreases pelvic rotation when the patient sits, henceforth puts the coccyx at a greater risk for luxation, which is a typical post-traumatic lesion.\(^\text{25}\) Instability of the coccyx can be judged radiologically as hypermobility or intermittent subluxation on dynamic sitting views via the method suggested by Maigne and Tamalet.\(^\text{18}\) Radiologically-demonstrable instability of the coccyx forms the group which has the maximum chance of recovery after surgery.\(^\text{1-20}\)

Some rare, though well-described, pathological conditions which can present as coccygodynia include recent fracture (post-traumatic or intrapartum),\(^\text{21}\) dislocation,\(^\text{22}\) tumours of the sacrum and coccyx (haemangioma,\(^\text{4}\) carcinoid,\(^\text{19}\), glomus tumours of the...
pericoccygeal tissue, lumbosacral intradural tumours (schwannoma, ependymoma, arachnoid cysts, perineural cyst, intraosseous lipoma, infectious diseases (tuberculosis, anal duct/gland cyst) and avascular necrosis of the coccyx. Glomus tumour as a cause of coccygodynia has been questioned as they mostly represent normal coccygeal bodies (non-pathological organelle glomus coccygeum). Immunohistochemical demonstration of the smooth muscle actin and neuron-specific enolase in glomus cells may be beneficial for accurate identification of this organelle.

In our case, MR imaging revealed a precoccygeal cystic lesion, and the histopathological diagnosis was epidermal inclusion cyst. An epidermal inclusion cyst can be described as a dermal cystic enclosure of keratinising squamous epithelium that is filled with keratin. Pathogenetically, an epidermal cyst may be secondary to congenital development or iatrogenic implantation. Our case appears to be of the congenital variety, in the absence of any antecedent trauma or local injections. Epidermal cyst in this region is an extremely rare condition. Clinically, these cysts manifest as painless, slow-growing, well-circumscribed swellings and may occur at any time from adolescence to adult life, but they may become inflamed or secondarily infected, resulting in pain and tenderness. The epidermal cysts are generally characterised on MR imaging by variability of signal intensity between different cases, and at times between the different parts of the same cysts. Other features include the absence of the oedema in surrounding tissues, fairly well-defined limits and peripheral enhancement on gadolinium injection. The disparity in signal intensity is most likely related to the chemical state of cholesterol, or the relative composition of cholesterol and keratin makes the preoperative diagnosis difficult. Malignancy must be ruled out. Rarely, malignancies, including basal cell carcinoma, Bowen’s disease, squamous cell carcinoma, and even mycosis fungoides, have developed in epidermal cysts.

A variety of treatment modalities have been described for coccygodynia. As with any clinical condition, a correct diagnosis is most vital in treatment. This report suggests that precoccygeal epidermal inclusion cyst should be considered as one of the differential diagnosis of coccygodynia, besides other possible aetiologies of coccygodynia mentioned in the literature. A high level of suspicion is warranted before embarking on surgical treatment of intractable coccygodynia. It is suggested that the clinician rules out all possible aetiologies for successful treatment of intractable coccygodynia through further investigations, preferably using MR imaging.
